

The spread on these contracts dwarfs the edge they would have to capture

Real quoted bid/ask on the matched K1 contracts, dev window. One axis: all three are percentages of mid.

A round trip pays the half-spread twice - on entry and again on exit - so the cost hurdle is 37.5% (median) to 59.6% (mean) of mid.

Against a +3.85% mid-to-mid edge, the spread is roughly 10x to 15x larger. This is why the mid-based result is not capturable, and it is measured, not assumed: the surface pull contained no bid/ask at all, so no earlier K1 attempt could quantify it.

Source: data/processed/k1_trade_summary.json, written by src/37_k1_signal_construction_real_prices.py; the same values are logged in the K1 REAL PRICES per-trade block of results/gate_log.md and verified against it at build time. Bar identity carried by the category axis and direct value labels, not colour.
